I'll thoroughly validate this documentation and then explain each part with real-world use cases. Let me start by analyzing the architecture and implementation details.Perfect! I've analyzed the comprehensive guide. Now let me provide you with a detailed validation and explanation as your mentor.

📋 VALIDATION REPORT

✅ Architecture Strengths

1. **Solid Multi-Tenancy Design**: Using Docker containers per customer is industry-standard (similar to how Heroku, Railway, and Render work)
2. **Smart SSL Strategy**: Wildcard certificates solve the Let's Encrypt rate limit problem elegantly
3. **Security-First Approach**: Proper firewall rules, isolated containers, and credential management
4. **Scalable Foundation**: Port mapping system can handle 100+ customers before needing redesign

⚠️ Critical Issues Found

1. **Port Collision Risk**: The formula `BASE_PORT + parseInt(customerId)` is dangerous if customerIds aren't sequential numbers. Customer "abc" would fail.

2. **Race Condition**: Multiple simultaneous provisions could assign the same port. Needs atomic DB operations.

3. **Missing Monitoring**: No health checks, no alerts if containers crash, no resource usage tracking.

4. **Backup Strategy**: Zero mention of data persistence. If the server dies, all customer WhatsApp sessions are gone.

5. **Nginx Reload Issue**: Appending to `customer_map.conf` without locks could corrupt the file during concurrent provisions.

6. **Docker Compose Version**: `version: '3'` is deprecated. Should use Compose file format v3.8+ or remove version key entirely.

🎓 DETAILED EXPLANATION WITH REAL-WORLD USE CASES

Let me break down each component like I'm teaching you in person:

---

1. THE CORE CONCEPT: "The Tunnel"

What it really means:

Imagine you own an apartment building. Each tenant (customer) gets their own apartment (Docker container). But there's only ONE main entrance (your domain). You need a smart receptionist (Nginx) who knows which apartment each visitor should go to.

Real-World Use Case:

Customer Sarah buys your service:
- She gets: customer-sarah.clawcloud.com
- Behind the scenes: Her WhatsApp bot runs in container on port 19001
- When she visits her URL: Nginx sees "sarah" and routes to port 19001
- She never knows about ports, Docker, or technical stuff

Why this matters:

- Sarah can bookmark her URL
- You can move her to a different server later
- If her container crashes, you restart it without changing her URL
- You can upgrade your infrastructure without affecting her

---

2. STEP 1: INFRASTRUCTURE (The Foundation)

A) Wildcard SSL Certificate

The Problem Without It:

Let's Encrypt allows ~50 certificates per domain per week. If you get 100 customers in a day, you'd hit the limit by customer #50 and customers #51-100 would get security errors.

The Solution:

One certificate that covers:

- `*.clawcloud.com` (all subdomains)
- `customer1.clawcloud.com`
- `customer2.clawcloud.com`
- `customer999.clawcloud.com`

Real-World Analogy:

Instead of getting a separate driver's license for every car you drive, you get ONE license that works for all vehicles. Same concept.

Validation Note: ✅ Cloudflare DNS integration is correct. This is the industry standard.

B) Nginx Configuration

What's happening in that config:

```
map $host $backend_port {
    hostnames;
    default 18789;
    include /etc/nginx/customer_map.conf;
}
```

Translation:

- "When someone visits `customerX.clawcloud.com`, look up X in my mapping file"
- "Find the port number for X"
- "Send the traffic there"

Real-World Use Case:

customer101.clawcloud.com arrives at Nginx
↓
Nginx checks customer_map.conf
↓
Finds: "customer101.clawcloud.com 19101;"
↓
Proxies traffic to localhost:19101 (the Docker container)
↓
Customer sees their WhatsApp dashboard

Critical Detail - WebSocket Support:

```
proxy_http_version 1.1;
proxy_set_header Upgrade $http_upgrade;
proxy_set_header Connection "upgrade";
```

Why this matters: WhatsApp QR codes need real-time bidirectional communication. Without this, the QR code wouldn't update when scanned.

Real Analogy: Regular HTTP is like sending letters. WebSockets are like having a phone call - both sides can talk anytime.

---

3. STEP 2: THE PROVISIONING ENGINE

This is the "magic factory" that creates customer environments.

What happens when someone pays $20:

Phase 1: Request Arrives

```
POST http://your-server:3000/provision
{
  "customerId": "101",
  "openaiKey": "sk-proj-..."
}
```

Phase 2: Create Customer Workspace

```
mkdir -p /opt/users/101/config
```

Think of this like creating a new employee's office. They get:

- A desk (directory)
- A filing cabinet (config folder)
- Security badge (password)

Phase 3: Generate Docker Environment

The code creates a `docker-compose.yml` file:

```
version: '3'
services:
  openclaw:
    image: openclaw/openclaw:latest
    container_name: claw-101
    restart: always
    ports:
      - "19101:18789"  # External:Internal
    volumes:
      - ./config:/root/.openclaw  # Persistent storage
    environment:
      - OPENCLAW_API_PASSWORD=xyz123
      - OPENAI_API_KEY=sk-...
```

Real-World Translation:

Docker Concept	Real-World Analogy
`image`	The apartment blueprint/template
`container_name`	The apartment number
`ports`	The apartment's private entrance
`volumes`	The apartment's personal storage that survives even if you remodel
`environment`	Keys and access codes

The Critical `restart: always` Flag:

Imagine customer 101's bot crashes at 3 AM because WhatsApp's API hiccupped. With `restart: always`, Docker automatically brings it back online in seconds. Without it, their service is down until you manually fix it.

Phase 4: Update the "Receptionist" (Nginx)

```
const mapEntry = `customer101.clawcloud.com 19101;\n`;
fs.appendFileSync('/etc/nginx/customer_map.conf', mapEntry);
await execPromise('systemctl reload nginx');
```

⚠️ **VALIDATION ISSUE:** This has a race condition!

The Problem:

Customer A provisions at 10:00:00.000
Customer B provisions at 10:00:00.001
Both try to append to customer_map.conf simultaneously
File gets corrupted: "customer1customer2.clawcloud.com 1910119102;"

The Fix:

```
// Use file locking
const lockfile = require('proper-lockfile');

const release = await lockfile.lock('/etc/nginx/customer_map.conf');
try {
  fs.appendFileSync('/etc/nginx/customer_map.conf', mapEntry);
  await execPromise('systemctl reload nginx');
} finally {
  await release();
}
```

---

4. STEP 3: THE USER EXPERIENCE

Let me walk you through what Sarah experiences:

Day 1: Purchase

1. **Sarah visits your website** and sees:
    - "Turn your WhatsApp into an AI assistant - $20/month"
    - She clicks "Buy Now"

Behind the scenes (0-30 seconds):

```
Stripe webhook → Your billing code → POST /provision
→ Creates claw-sarah container
→ Assigns customer-sarah.clawcloud.com
→ Generates password: "k8jx9p2m"
```

2.

Sarah receives email:

```
Welcome to ClawCloud!

Your Dashboard: https://customer-sarah.clawcloud.com
Password: k8jx9p2m

Next Steps:
1. Click the link above
2. Enter your password
3. Connect your WhatsApp
```

3.

Day 1: Setup (5 minutes)
Sarah clicks the link and sees a clean dashboard:

```
┌──────────────────────────────────┐
│ 🤖 ClawCloud Dashboard           │
├──────────────────────────────────┤
│ Status: ⚪ Not Connected          │
│                                  │
│ [Connect WhatsApp]               │
└──────────────────────────────────┘
```

4.

She clicks "Connect WhatsApp" and sees:

```
┌──────────────────────────────────────┐
│ 📱 Scan this QR Code                 │
│                                      │
│   ▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄                  │
│   ▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄                  │
│   ▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄                  │
│   ▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄                  │
│   ▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄                  │
│   ▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄▄                  │
│                                      │
│ Open WhatsApp > Linked Devices       │
│ > Link a Device                      │
└──────────────────────────────────────┘
```

5.
6. **She scans with her phone:**
    - WhatsApp asks: "Link this device?"
    - She taps "Link"
    - The QR code disappears
    - Dashboard shows: "Status: 🟢 Connected"

Day 1-365: Daily Use

Sarah texts her WhatsApp:

Sarah: "Summarize my emails from today"[3 seconds later]AI Bot: "You received 12 emails:- 5 newsletters (archived)- 3 work projects (flagged)- 2 personal (summarized below)- 2 spam (deleted)Key action items:1. Review Q4 budget by Friday2. Confirm dinner with Mike..."

7.

What's happening behind the scenes:

```
Sarah's Phone → WhatsApp Servers
          ↓
WhatsApp Servers → POST https://customer-sarah.clawcloud.com/webhook
          ↓
Nginx → Routes to localhost:19101 (Sarah's container)
          ↓
OpenClaw receives message → Calls OpenAI API (using Sarah's key)
          ↓
Gets response → Sends back via WhatsApp API
          ↓
Sarah's Phone receives reply
```

---

5. THE MARKETPLACE & SERVICE LAYER

This is where it gets really powerful. Let me explain with a story:

Month 2: Sarah Wants More Features

Sarah's basic WhatsApp bot is great, but she wants it to:

- Write code
- Schedule meetings
- Track her sales pipeline

Old Way (Bad):

- Sarah emails support
- You manually edit her container
- Takes 2 days
- Not scalable to 1000 customers

New Way (Your System):

Sarah visits her dashboard:

```
┌──────────────────────────────────────────────────────────┐
│ 🏪 Marketplace                                           │
├──────────────────────────────────────────────────────────┤
│                                                          │
│  ┌──────────────────────┐  ┌──────────────────────┐     │
│  │ 💻 Coding Agent      │  │ 📅 Calendar          │     │
│  │ $5/month             │  │ Free                 │     │
│  │ [Install]            │  │ [Installed ✓]        │     │
│  └──────────────────────┘  └──────────────────────┘     │
│                                                          │
│  ┌──────────────────────┐  ┌──────────────────────┐     │
│  │ 📊 Sales CRM         │  │ 📧 Email             │     │
│  │ $10/month            │  │ $3/month             │     │
│  │ [Install]            │  │ [Install]            │     │
│  └──────────────────────┘  └──────────────────────┘     │
└──────────────────────────────────────────────────────────┘
```

She clicks "Install" on Coding Agent.

What happens (in 5 seconds):

```
// Frontend sends:
POST /api/install-skill
{
  "userId": "sarah",
  "skillId": "coding"
}
```

// Backend:
1. Reads template: /opt/templates/coding.json
2. Copies to: /opt/users/sarah/config/skills/coding.json
3. Adds Python sandbox container to sarah's docker-compose.yml
4. Restarts containers: docker-compose up -d
5. Returns: "Coding Agent Installed ✓"

Now Sarah can text:

Sarah: "Write a Python script to analyze my CSV sales data"

AI Bot: "I've created a script for you:

[Sends Python code]

Would you like me to:
1. Run it on sample data?
2. Explain how it works?
3. Schedule it to run daily?"

---

6. THE "EMPLOYEES" FEATURE

This is brilliant. Let me explain:

The Concept:

Instead of ONE AI personality, Sarah can create multiple "employees" with different roles.

Real-World Use Case:

Sarah creates:

1. "Marketing Mary"
   - Role: Social Media Manager
   - Prompt: "You're an expert marketer. Generate Instagram captions..."
   - Triggered by: Messages starting with "Marketing:"

2. "Dev Dan"
   - Role: Senior Developer
   - Prompt: "You're a Python expert. Write production-ready code..."
   - Triggered by: Messages starting with "Code:"

3. "Sales Sam"
   - Role: Sales Assistant
   - Prompt: "You track deals, follow up with leads..."

- Triggered by: Messages starting with "Sales:"

Sarah's workflow:

Morning text to WhatsApp:

"Marketing: Create 5 posts for our product launch"
→ Marketing Mary generates creative content

"Sales: What deals close this week?"
→ Sales Sam checks CRM and lists 3 deals

"Code: Debug my API endpoint"
→ Dev Dan analyzes code and suggests fixes

Backend Implementation:

```
// In agents.json:
[
  {
    "id": "emp_1706123456",
    "name": "Marketing Mary",
    "role": "marketing",
    "system_prompt": "You're an expert marketer...",
    "active": true,
    "trigger": "Marketing:"
  },
  {
    "id": "emp_1706123789",
    "name": "Dev Dan",
    "role": "developer",
    "system_prompt": "You're a Python expert...",
    "active": true,
    "trigger": "Code:"
  }
]

// OpenClaw routing logic:
incoming_message = "Marketing: Create 5 posts..."

for agent in agents:
    if incoming_message.startsWith(agent.trigger):
        response = call_llm(agent.system_prompt, incoming_message)
        send_to_whatsapp(response)
```

---

7. SECURITY & PRODUCTION CONCERNS

Let me explain the "Don't Get Hacked" checklist:

A) Firewall Configuration

The Risk:

Your provisioning API runs on port 3000. If exposed publicly:

```
Attacker: POST http://your-server:3000/provision
{
  "customerId": "hacker",
  "openaiKey": "THEIR_KEY"
}
```

Result: Free container on your server, costs you money

The Fix:

```
# Block port 3000 from internet
ufw deny 3000

# Only allow from your billing server
ufw allow from YOUR_BILLING_SERVER_IP to any port 3000

# Or if billing is on same server, only allow localhost
# (Your billing code uses http://localhost:3000)
```

B) Swap File

Why 8GB Swap?

Scenario:

- You have 50 customers
- Each container normally uses 200MB RAM
- Total: 10GB (fine on your 16GB server)

3 AM on Black Friday:

- All 50 customers' bots get flooded with messages
- Each container spikes to 400MB
- Total needed: 20GB
- You have: 16GB
- **Without swap: Server crashes, ALL customers go offline**
- **With 8GB swap: Server slows down but stays online**

The Command:

```
# Create 8GB swap file
fallocate -l 8G /swapfile
chmod 600 /swapfile
mkswap /swapfile
swapon /swapfile

# Make permanent
echo '/swapfile none swap sw 0 0' >> /etc/fstab
```

C) Docker Log Rotation

The Problem:

Customer logs can fill your disk:

Container logs after 30 days: 50GB
Container logs after 90 days: 150GB
Container logs after 1 year: 600GB (DISK FULL → CRASH)

The Fix:

Update your docker-compose template:

```
services:
  openclaw:
    image: openclaw/openclaw:latest
    logging:
      driver: "json-file"
      options:
        max-size: "10m"    # Each log file max 10MB
        max-file: "3"      # Keep only 3 files
        # Total per container: 30MB max
```

---

8. SCALING CONSIDERATIONS

Current Architecture Limits:

Resource	Limit	When You Hit It
Ports	~46,000 available	46,000 customers
RAM (16GB)	~80 containers	80 customers (200MB each)

CPU	~50 active users	50 customers texting simultaneously
Nginx map file	~10,000 lines	10,000 customers

When to Upgrade:

At 50 customers:

- Upgrade to CX51 (32GB RAM)
- Add monitoring (Prometheus + Grafana)
- Set up automated backups

At 200 customers:

- Move to database-driven port assignment (PostgreSQL)
- Implement load balancer (HAProxy)
- Consider Kubernetes migration

At 1000+ customers:

- Multi-server setup
- Kubernetes orchestration
- Separate database server
- CDN for static assets

🎯 CRITICAL IMPROVEMENTS NEEDED

1. Database Schema (Missing)

You need this IMMEDIATELY:

```
CREATE TABLE customers (
    id SERIAL PRIMARY KEY,
    customer_id VARCHAR(50) UNIQUE NOT NULL,
    subdomain VARCHAR(100) UNIQUE NOT NULL,
    port INTEGER UNIQUE NOT NULL,
    password VARCHAR(100) NOT NULL,
    openai_key TEXT,
    telegram_token TEXT,
    status VARCHAR(20) DEFAULT 'active',
    created_at TIMESTAMP DEFAULT NOW(),
    last_active TIMESTAMP
);

CREATE TABLE skills (
```

```
    id SERIAL PRIMARY KEY,
    customer_id VARCHAR(50) REFERENCES customers(customer_id),
    skill_id VARCHAR(50) NOT NULL,
    installed_at TIMESTAMP DEFAULT NOW(),
    status VARCHAR(20) DEFAULT 'active'
);

CREATE TABLE agents (
    id SERIAL PRIMARY KEY,
    customer_id VARCHAR(50) REFERENCES customers(customer_id),
    agent_name VARCHAR(100) NOT NULL,
    role VARCHAR(50),
    system_prompt TEXT,
    created_at TIMESTAMP DEFAULT NOW()
);
```

Updated Provisioning Code:

```
app.post('/provision', async (req, res) => {
    const { customerId, openaiKey } = req.body;

    // 1. Get next available port from database (ATOMIC)
    const result = await db.query(`
        INSERT INTO customers (customer_id, subdomain, port, password, openai_key)
        VALUES ($1, $2,
            (SELECT COALESCE(MAX(port), 19000) + 1 FROM customers),
            $3, $4
        )
        RETURNING *
    `, [
        customerId,
        `customer${customerId}.${DOMAIN}`,
        generatePassword(),
        openaiKey
    ]);

    const { port, subdomain, password } = result.rows[0];

    // 2. Rest of provisioning logic...
});
```

2. Health Monitoring

Add this to each container:

```
services:
```

```
  openclaw:
    # ... existing config ...
    healthcheck:
      test: ["CMD", "curl", "-f", "http://localhost:18789/health"]
      interval: 30s
      timeout: 10s
      retries: 3
      start_period: 40s
```

Create monitoring endpoint:

```
// Add to your manager API
app.get('/api/health-check', async (req, res) => {
    const containers = await execPromise('docker ps --format "{{.Names}},{{.Status}}"');
    const lines = containers.split('\n').filter(l => l.startsWith('claw-'));

    const unhealthy = lines.filter(line => !line.includes('healthy'));

    if (unhealthy.length > 0) {
        // Send alert to your phone/Slack
        await sendAlert(`${unhealthy.length} containers unhealthy`);
    }

    res.json({ total: lines.length, unhealthy: unhealthy.length });
});
```

3. Backup Strategy

Critical Data to Backup:

```
# Customer configurations
/opt/users/*/config/

# Database
PostgreSQL dump

# Nginx mappings
/etc/nginx/customer_map.conf
```

Automated Backup Script:

```
#!/bin/bash
# /opt/backups/daily-backup.sh

BACKUP_DIR="/opt/backups/$(date +%Y-%m-%d)"
mkdir -p $BACKUP_DIR
```

```
# Backup all customer configs
tar -czf $BACKUP_DIR/customer-configs.tar.gz /opt/users/

# Backup database
pg_dump clawcloud > $BACKUP_DIR/database.sql

# Upload to S3/Backblaze
aws s3 sync $BACKUP_DIR s3://your-backup-bucket/$(date +%Y-%m-%d)/

# Keep only last 30 days locally
find /opt/backups/ -mtime +30 -delete
```

Add to crontab:

```
0 2 * * * /opt/backups/daily-backup.sh
```

📊 COST ANALYSIS

Let me break down the economics:

Your Costs:

Item	Monthly Cost
Hetzner CX41	€17 (~$18)
Domain	$1/month
Backups (S3)	$3-5/month
Total	**~$22-24/month**

Customer Pricing:

- Basic: $20/month (WhatsApp bot only)
- Pro: $35/month (+ Marketplace skills)
- Business: $75/month (+ Multiple employees)

Break-Even:

- At 2 customers: Profitable
- At 10 customers: $200/month revenue, $24 costs = **88% margin**
- At 50 customers: $1,000/month revenue = **$976 profit**

When to upgrade server:

- Revenue > $500/month → Upgrade to CX51 (€30/month)
- Still maintaining >90% margins

✅ FINAL VALIDATION CHECKLIST

Before going live, ensure:

- [ ] Wildcard SSL installed and auto-renewing
- [ ] Database with atomic port assignment
- [ ] Firewall configured (port 3000 blocked)
- [ ] Swap file created (8GB minimum)
- [ ] Docker log rotation enabled
- [ ] Backup script running daily
- [ ] Health monitoring endpoint created
- [ ] Nginx reload uses file locking
- [ ] Test provisioning 5 customers simultaneously
- [ ] Test container crash recovery (kill a container, verify restart)
- [ ] Test full server reboot (all containers should auto-start)
- [ ] Legal: Terms of Service + Privacy Policy
- [ ] Stripe webhook handler with signature verification

🚀 YOUR NEXT STEPS

Week 1: Foundation

1. Set up Hetzner server
2. Configure wildcard SSL
3. Deploy basic provisioning API
4. Test with 3 test customers

Week 2: Backend

1. Set up PostgreSQL
2. Implement skill marketplace
3. Create health monitoring
4. Set up backups

Week 3: Frontend

1. Build customer dashboard (React)
2. Add Stripe integration
3. Create marketplace UI

Week 4: Launch

1. Beta test with 10 users
2. Monitor for issues
3. Iterate based on feedback

This documentation is **85% production-ready**. The architecture is solid, but you need the database layer and monitoring before handling real customers. The core "tunnel" concept is excellent and will scale to your first 100 customers easily.

Want me to build any specific component for you? I can create:

- A) Complete database schema + migration scripts
- B) Full Node.js backend with all endpoints
- C) React dashboard component
- D) Stripe webhook handler

Which would be most helpful right now?

PRODUCTION VALIDATION REPORT - SIMPLIFIED

✅ WHAT'S CORRECT

1. **Wildcard SSL approach** - Correct, avoids Let's Encrypt rate limits
2. **Docker isolation** - Each customer gets separate container, good security
3. **Nginx reverse proxy** - Standard industry approach for routing
4. **WebSocket support** - Required for WhatsApp QR code functionality
5. **Auto-restart containers** - Handles crashes automatically
6. **Volume mounting** - Data persists even if container restarts

❌ CRITICAL PROBLEMS

1. **No database** - Port assignment will break with concurrent users
2. **Race conditions** - Multiple provisions at same time will corrupt files
3. **No monitoring** - You won't know when containers crash
4. **No backups** - Server failure = all customer data lost

5. **Weak security** - Port 3000 exposed means anyone can provision free containers
6. **Port formula broken** - `BASE_PORT + customerId` only works if customerId is a number

---

FLOW DIAGRAM EXPLANATIONS

FLOW 1: CUSTOMER PROVISIONING (User Buys Service)

User pays $20
↓
Stripe webhook triggers
↓
POST /provision {customerId: "101", openaiKey: "sk-..."}
↓
Backend creates directory: /opt/users/101/
↓
Backend writes docker-compose.yml file
↓
Backend runs: docker-compose up -d
↓
Container starts on port 19101
↓
Backend adds to Nginx map: "customer101.clawcloud.com 19101;"
↓
Backend reloads Nginx
↓
Returns: {url: "https://customer101.clawcloud.com", password: "xyz"}
↓
User receives email with URL and password

What each step does:

- **Directory creation**: Creates isolated folder for customer's data
- **docker-compose.yml**: Configuration file telling Docker what to run
- **docker-compose up**: Actually starts the container
- **Port 19101**: External port on your server mapped to internal port 18789 in container
- **Nginx map update**: Tells Nginx "when customer101.clawcloud.com arrives, send to port 19101"
- **Nginx reload**: Applies the new routing rule without downtime

---

FLOW 2: WHATSAPP CONNECTION (User Connects Phone)

User opens https://customer101.clawcloud.com
↓
Nginx receives request
↓
Nginx checks map file, finds port 19101
↓
Nginx forwards request to localhost:19101
↓
Container's web UI responds with QR code page
↓
User scans QR code with phone
↓
WhatsApp app sends credentials to container via WebSocket
↓
Container establishes persistent connection to WhatsApp servers
↓
Container registers webhook: "Send all my messages to https://customer101.clawcloud.com/webhook"
↓
Connection complete, dashboard shows "Connected"

Key technical points:

- **WebSocket**: Two-way real-time communication channel (not regular HTTP)
- **Persistent connection**: Container maintains open connection to WhatsApp servers
- **Webhook**: WhatsApp will POST incoming messages to this URL
- **QR code**: Contains encrypted session token, scanned phone becomes linked device

---

FLOW 3: MESSAGE PROCESSING (User Sends WhatsApp Message)

User texts WhatsApp: "Summarize my emails"
↓
WhatsApp servers receive message
↓
WhatsApp servers POST to: https://customer101.clawcloud.com/webhook
↓
Nginx receives POST request
↓
Nginx routes to localhost:19101 (container)
↓

Container's OpenClaw code receives webhook
↓
OpenClaw extracts message text
↓
OpenClaw calls OpenAI API with user's key: "Summarize my emails"
↓
OpenAI returns response text
↓
OpenClaw sends response via WhatsApp API
↓
WhatsApp servers deliver to user's phone
↓
User sees AI response

Processing details:

- **Webhook payload**: JSON containing sender, message text, timestamp
- **OpenAI API call**: Uses customer's own API key (from environment variable)
- **Response timing**: Usually 2-5 seconds total
- **Error handling**: If OpenAI fails, container can retry or send error message

---

FLOW 4: SKILL INSTALLATION (User Buys Coding Agent)

User clicks "Install Coding Agent" in dashboard
↓
Frontend sends: POST /api/install-skill {userId: "101", skillId: "coding"}
↓
Backend reads template: /opt/templates/coding.json
↓
Backend copies to: /opt/users/101/config/skills/coding.json
↓
Backend checks if skill needs Docker sidecar
↓
If yes: Backend updates docker-compose.yml, adds python-sandbox container
↓
Backend runs: docker-compose up -d (starts new sidecar)
↓
Backend restarts main container: docker restart claw-101
↓
Container reads new skill config on startup
↓
Returns: "Coding Agent Installed"
↓
User can now ask: "Write Python script to analyze CSV"

Sidecar container explanation:

- **Main container**: Runs OpenClaw (WhatsApp bot logic)
- **Sidecar container**: Runs Python sandbox (isolated code execution)
- **Communication**: Main container sends code to sidecar via HTTP
- **Isolation**: If Python code crashes, main container unaffected

---

FLOW 5: TELEGRAM CONNECTION (Alternative to WhatsApp)

User creates bot with @BotFather on Telegram
↓
BotFather gives token: "12345:ABC..."
↓
User enters token in dashboard
↓
POST /api/connect/telegram {userId: "101", token: "12345:ABC..."}
↓
Backend writes to: /opt/users/101/config/secrets.json
↓
Backend restarts container
↓
Container reads token on startup
↓
Container calls Telegram API: setWebhook
↓
Registers: https://customer101.clawcloud.com/webhook/telegram
↓
Telegram servers now POST messages to that URL
↓
Same flow as WhatsApp from here

Telegram differences:

- **No QR code**: Uses token-based authentication
- **Webhook setup**: Done programmatically via API
- **Multiple platforms**: Same container can handle WhatsApp + Telegram simultaneously

---

TECHNICAL COMPONENT BREAKDOWN

1. NGINX REVERSE PROXY

What it does: Routes incoming HTTPS requests to the correct Docker container

How it works:

```
# Map subdomains to ports
map $host $backend_port {
    customer101.clawcloud.com 19101;
    customer102.clawcloud.com 19102;
    customer103.clawcloud.com 19103;
}

# Receive HTTPS traffic
server {
    listen 443 ssl;

    # Forward to container
    location / {
        proxy_pass http://127.0.0.1:$backend_port;
    }
}
```

Why dynamic mapping:

- Can't hardcode 1000 customers
- Map file updated automatically when new customer provisions
- Nginx reload applies changes without downtime

---

2. DOCKER CONTAINERS

What each customer gets:

```
services:
  openclaw:
    image: openclaw/openclaw:latest        # The application
    container_name: claw-101               # Unique identifier
    ports:
      - "19101:18789"                      # External:Internal
    volumes:
      - ./config:/root/.openclaw           # Persistent storage
```

```
    environment:
      - OPENCLAW_API_PASSWORD=xyz          # Web UI password
      - OPENAI_API_KEY=sk-...              # Customer's API key
    restart: always                        # Auto-restart on crash
```

Resource limits (should add):

```
deploy:
  resources:
    limits:
      cpus: '0.5'      # Max 50% of one CPU core
      memory: 512M     # Max 512MB RAM
    reservations:
      memory: 128M     # Guaranteed 128MB
```

---

3. FILE SYSTEM STRUCTURE

```
/opt/

```

---

4. PROVISIONING API ENDPOINTS

POST /provision

Creates new customer environment

Input:

```
{
  "customerId": "101",
  "openaiKey": "sk-..."
}
```

Process:

1. Assign port (19000 + customerId)
2. Create directory structure
3. Generate docker-compose.yml
4. Start container
5. Update Nginx map
6. Reload Nginx

Output:

```
{
  "status": "success",
  "url": "https://customer101.clawcloud.com",
  "password": "xyz123"
}
```

POST /api/connect/telegram

Connects Telegram bot

Input:

```
{
  "userId": "101",
  "token": "12345:ABC..."
}
```

Process:

1. Write token to secrets.json
2. Restart container

3. Container auto-registers webhook

Output:

```
{
  "status": "success",
  "message": "Telegram Connected"
}
```

POST /api/install-skill

Adds capability to customer container

Input:

```
{
  "userId": "101",
  "skillId": "coding"
}
```

Process:

1. Read template from /opt/templates/coding.json
2. Copy to customer's skills folder
3. If needs sidecar, update docker-compose.yml
4. Restart containers

Output:

```
{
  "status": "success",
  "message": "Coding Agent Installed"
}
```

POST /api/add-employee

Creates new AI persona

Input:

```
{
  "userId": "101",
  "employeeName": "Marketing Mary",
  "role": "marketing",
```

```
  "prompt": "You are an expert marketer..."
}
```

Process:

1. Read existing agents.json
2. Add new agent with unique ID
3. Write back to file
4. Restart container

Output:

```
{
  "status": "success",
  "message": "Employee Marketing Mary Hired"
}
```

SECURITY ANALYSIS

✅ WHAT'S SECURE

1. **Container isolation** - Customers can't access each other's data
2. **HTTPS everywhere** - Wildcard SSL encrypts all traffic
3. **No shared ports** - Each customer has unique port
4. **Volumes only** - Containers can't write to host filesystem
5. **API keys in environment** - Not hardcoded in code

❌ SECURITY HOLES

1. **Port 3000 exposed** - Anyone can provision containers
    - Fix: `ufw deny 3000`, only allow from billing server IP
2. **No rate limiting** - Attacker can spam provisions
    - Fix: Add rate limiter to API
3. **No input validation** - SQL injection possible if using DB
    - Fix: Use parameterized queries
4. **No authentication on API** - No API key required
    - Fix: Add API key header check

5. **Customer can see password in email** - Insecure
    - Fix: Force password change on first login
6. **No container resource limits** - Customer can consume all CPU/RAM
    - Fix: Add Docker resource limits

SCALING LIMITS

CURRENT ARCHITECTURE

Resource	Limit	Calculation
Available ports	46,535	Ports 19000-65535
RAM	80 customers	16GB ÷ 200MB per container
CPU	50 active	8 cores ÷ 0.15 per active user
Disk I/O	100 customers	SSD can handle ~100 concurrent writes
Nginx map	10,000 lines	Performance degrades after this

WHEN TO UPGRADE

At 50 customers:

- Upgrade server to 32GB RAM (€30/month)
- Add monitoring (Prometheus)
- Implement proper database

At 100 customers:

- Multiple servers with load balancer
- Separate database server
- Kubernetes for orchestration

At 500 customers:

- Multi-region deployment
- CDN for static assets
- Dedicated ops team

MISSING COMPONENTS

1. DATABASE SCHEMA (CRITICAL)

```
CREATE TABLE customers (
    id SERIAL PRIMARY KEY,
    customer_id VARCHAR(50) UNIQUE,
    subdomain VARCHAR(100) UNIQUE,
    port INTEGER UNIQUE,
    password VARCHAR(100),
    created_at TIMESTAMP DEFAULT NOW()
);

CREATE INDEX idx_port ON customers(port);
CREATE INDEX idx_subdomain ON customers(subdomain);
```

Why needed:

- Atomic port assignment (no duplicates)
- Track which ports are used
- Prevent race conditions
- Enable customer management dashboard

---

2. MONITORING (CRITICAL)

```
// Health check endpoint
app.get('/api/health', async (req, res) => {
    const result = await exec('docker ps --format "{{.Names}},{{.Status}}"');
    const containers = result.stdout.split('\n');

    const unhealthy = containers.filter(c =>
        c.startsWith('claw-') && !c.includes('Up')
    );

    if (unhealthy.length > 0) {
        sendAlert(`${unhealthy.length} containers down`);
    }

    res.json({
        total: containers.length,
        healthy: containers.length - unhealthy.length,
```

```
        unhealthy: unhealthy.length
    });
});
```

Run every minute:

```
* * * * * curl http://localhost:3000/api/health
```

---

3. BACKUP SYSTEM (CRITICAL)

```
#!/bin/bash
# Daily backup script

# Backup customer configs
tar -czf /backups/configs-$(date +%Y%m%d).tar.gz /opt/users/

# Backup database
pg_dump clawcloud > /backups/db-$(date +%Y%m%d).sql

# Upload to cloud storage
aws s3 sync /backups/ s3://your-bucket/backups/

# Delete local backups older than 7 days
find /backups/ -mtime +7 -delete
```

Cron job:

```
0 2 * * * /opt/scripts/backup.sh
```

---

4. ERROR HANDLING (MISSING)

Current code has no try-catch in critical places:

```
// BAD - No error handling
app.post('/provision', async (req, res) => {
    const userPort = BASE_PORT + parseInt(req.body.customerId);
    await execPromise(`docker-compose up -d`);
    res.json({ status: 'success' });
});

// GOOD - Proper error handling
app.post('/provision', async (req, res) => {
```

```
    try {
        // Validate input
        if (!req.body.customerId) {
            return res.status(400).json({ error: 'customerId required' });
        }

        // Check if already exists
        const exists = await checkCustomerExists(req.body.customerId);
        if (exists) {
            return res.status(409).json({ error: 'Customer already exists' });
        }

        // Assign port atomically from DB
        const port = await assignPort(req.body.customerId);

        // Create container
        await createContainer(req.body.customerId, port);

        res.json({ status: 'success', port });

    } catch (error) {
        console.error('Provision failed:', error);

        // Cleanup on failure
        await cleanup(req.body.customerId);

        res.status(500).json({
            error: 'Provisioning failed',
            message: error.message
        });
    }
});
```

COST BREAKDOWN

YOUR COSTS (Monthly)

Item	Cost
Hetzner CX41 (16GB)	$18
Domain (.com)	$1

Backups (S3/Backblaze)	$5
Total	**$24**

CUSTOMER PRICING

Plan	Price	Margin
Basic	$20	$20 - $0.24 = $19.76 (98.8%)
Pro	$35	$35 - $0.24 = $34.76 (99.3%)
Business	$75	$75 - $0.24 = $74.76 (99.7%)

Cost per customer: $24 ÷ 100 customers = $0.24/customer

Break-even: 2 customers

At 100 customers:

- Revenue: $2,000/month (100 × $20)
- Costs: $24/month
- Profit: $1,976/month (98.8% margin)

DEPLOYMENT CHECKLIST

Phase 1: Server Setup

- [ ] Buy domain
- [ ] Point DNS to Cloudflare
- [ ] Rent Hetzner CX41
- [ ] Install Docker, Nginx, Certbot
- [ ] Generate wildcard SSL certificate
- [ ] Configure Nginx reverse proxy
- [ ] Create 8GB swap file
- [ ] Configure firewall (ufw)

Phase 2: Backend

- [ ] Deploy Node.js provisioning API
- [ ] Set up PostgreSQL database

- [ ] Create database schema
- [ ] Implement health monitoring
- [ ] Set up backup script
- [ ] Add error logging

Phase 3: Testing

- [ ] Provision test customer
- [ ] Connect WhatsApp
- [ ] Send test messages
- [ ] Install test skill
- [ ] Kill container, verify auto-restart
- [ ] Reboot server, verify auto-start
- [ ] Test concurrent provisioning

Phase 4: Launch

- [ ] Deploy frontend dashboard
- [ ] Integrate Stripe billing
- [ ] Write Terms of Service
- [ ] Set up support system
- [ ] Beta test with 10 users

FINAL VERDICT

Architecture Quality: B+ (85%)

Strengths:

- Core tunnel concept is solid
- Docker isolation is industry-standard
- Wildcard SSL solves rate limit problem
- Auto-restart handles crashes

Weaknesses:

- No database (critical)
- No monitoring (critical)
- No backups (critical)
- Security gaps (fixable)

Production Readiness: NOT READY

Must fix before launch:

1. Add PostgreSQL database
2. Implement atomic port assignment
3. Add health monitoring
4. Set up automated backups
5. Secure provisioning API
6. Add proper error handling

Timeline to production:

- With fixes: 2-3 weeks
- Without fixes: Will break at 10+ customers

Recommendation

DO NOT launch without:

- Database for port management
- Backup system
- Basic monitoring

Can launch with:

- Current architecture + above fixes
- Will handle 100 customers comfortably
- Can scale to 500 with server upgrade

Did you understand the flows and components? Want me to explain any specific part in more detail?

We have telegram and what'sapp , users can connect , i mean users can connect to any bot or both bots as required , as the user likes

HONEST ANSWER: EMAIL ACCESS PROBLEM

THE TRUTH

OpenClaw running in a Docker container on your server DOES NOT have access to the user's emails.

Let me explain why and what actually happens:

WHAT THE PDF DOESN'T TELL YOU

The PDF shows this example:

User: "Summarize my emails"
Bot: "You received 12 emails: 5 newsletters, 3 work projects..."

This is MISLEADING. Here's the reality:

HOW EMAIL ACCESS ACTUALLY WORKS

Option 1: User Must Give Gmail API Access

For the bot to read emails, you need:

1. User goes to Google Cloud Console
2. User creates OAuth credentials
3. User gives bot permission to read Gmail
4. User provides OAuth token to OpenClaw
5. OpenClaw uses Gmail API to fetch emails

Problems:

- Most users can't do this (too technical)
- Requires Google developer account
- OAuth tokens expire every 7 days
- User must manually refresh token

Option 2: User Must Install Gmail Skill

The bot needs a **skill** (plugin) that:

1. Has Gmail API integration code
2. User provides Gmail password or app password
3. Skill connects via IMAP protocol
4. Fetches emails on demand

This requires:

```
// In the container, there must be code like this:

const Imap = require('imap');

function fetchEmails(userEmail, userPassword) {
    const imap = new Imap({
        user: userEmail,
        password: userPassword,
        host: 'imap.gmail.com',
        port: 993,
        tls: true
    });

    imap.connect();
    // Fetch emails...
}
```

Problems:

- User must share Gmail password (security risk)
- Gmail blocks this by default (need "less secure apps")
- Requires additional skill installation
- Not mentioned in the PDF at all

Option 3: The Bot Can't Actually Do It

Most likely reality:

When user says "Summarize my emails", the bot responds:

"I don't have access to your emails. To enable this:

1. Install the Gmail Skill from marketplace
2. Provide your Gmail credentials
3. Then I can read and summarize your emails"

WHAT OPENCLAW ACTUALLY HAS ACCESS TO

Let me be brutally honest about what's possible **out of the box**:

✅ WHAT IT CAN DO (No Extra Setup)

1. **Answer general questions**
    - "What's the capital of France?"
    - "Explain quantum physics"
    - "Write a poem about cats"
2. **WhatsApp/Telegram only**
    - Read messages sent to the bot
    - Reply to messages
    - Send messages back
3. **Use AI to generate text**
    - Write code
    - Create content
    - Analyze text you send it

❌ WHAT IT CANNOT DO (Without Extra Skills/APIs)

1. **Read your emails** - NO
2. **Access your calendar** - NO
3. **Read your files** - NO
4. **Browse the web** - NO
5. **Control your phone** - NO
6. **Access other apps** - NO

THE MARKETPLACE "SKILLS" EXPLAINED

The PDF talks about installing "skills" like:

- Coding Agent
- Calendar
- Email

What this actually means:

Coding Skill

// Creates a Python sandbox container
// User sends: "Write Python to analyze CSV"
// Bot writes code
// Code runs in isolated container
// Returns results

✅ This CAN work - just runs code in Docker

Calendar Skill

// User must provide Google Calendar API token
// Skill code uses token to access calendar
// Creates/reads events via Google Calendar API

⚠️ This REQUIRES user to set up Google API credentials
⚠️ Most users can't do this

Email Skill

// User must provide Gmail credentials OR OAuth token
// Skill uses IMAP/Gmail API to fetch emails
// Parses and summarizes

⚠️ REQUIRES Gmail password or OAuth setup
⚠️ Security risk
⚠️ Gmail blocks this by default

THE REAL WORKFLOW FOR EMAIL ACCESS

Let me show you what **actually** needs to happen:

Step 1: User Installs Email Skill

User clicks "Install Email Skill" in marketplace
↓
System copies email-skill.json to container
↓
Container now has email integration code

Step 2: User Must Configure Credentials

In the dashboard, user sees:

```
┌──────────────────────────────────────────┐
│ 📧 Email Skill Settings                  │
├──────────────────────────────────────────┤
│ Gmail Address: [_____________]           │
│ App Password:  [_____________]           │
│                                          │
│ How to get App Password:                 │
│ 1. Go to myaccount.google.com            │
│ 2. Security → 2-Step Verification        │
│ 3. App passwords → Generate              │
```

```
│  4. Paste password above          │
│                                   │
│  [Save Credentials]               │
└──────────────────────────────────────────────┘
```

Step 3: Container Stores Credentials

```
// In /opt/users/101/config/secrets.json
{
  "telegram_token": "12345:ABC...",
  "gmail_email": "user@gmail.com",
  "gmail_app_password": "abcd efgh ijkl mnop"
}
```

Step 4: Skill Code Uses Credentials

```
// Inside container when user asks about emails:

const secrets = JSON.parse(fs.readFileSync('/root/.openclaw/secrets.json'));

const imap = new Imap({
    user: secrets.gmail_email,
    password: secrets.gmail_app_password,
    host: 'imap.gmail.com',
    port: 993,
    tls: true
});

imap.connect();
imap.openBox('INBOX', true, (err, box) => {
    // Fetch last 10 emails
    // Summarize with AI
    // Send summary back to user
});
```

THE PROBLEMS WITH THIS APPROACH

Security Issues

1. **Storing passwords on your server**

    - If your server gets hacked, all user Gmail passwords leaked
    - You're liable for data breach

2. **Gmail blocks this by default**
    - User must enable "less secure app access"
    - Google is deprecating this feature
3. **Credential management**
    - Passwords stored in plain text files
    - No encryption
    - Visible in Docker environment

Technical Issues

1. **Gmail API quota limits**
    - 1 billion requests/day (sounds like a lot)
    - But 1000 users checking email every hour = hits limit fast
2. **IMAP connection limits**
    - Gmail allows 15 simultaneous connections
    - If user checks email via phone + computer + bot = problems
3. **Token expiration**
    - OAuth tokens expire
    - User must re-authenticate frequently
    - Bad user experience

WHAT THE PDF SHOULD HAVE SAID

Honest version:

> "The bot can integrate with Gmail, Calendar, and other services, **but requires**:
>
> 1. User to install the specific skill from marketplace
> 2. User to provide API credentials or OAuth tokens
> 3. Skill code to be properly implemented with error handling
> 4. User to understand security implications
>
> Out of the box, the bot can only:
>
> - Respond to messages via WhatsApp/Telegram
> - Use AI to generate text
> - Execute code in sandboxed environment
>
> All other integrations require additional setup."

ALTERNATIVES THAT ACTUALLY WORK

Option 1: Email Forwarding

Instead of bot accessing Gmail:

User sets up Gmail filter:
"All emails → Forward to bot@clawcloud.com"
↓
Your server receives emails via SMTP
↓
Bot processes and sends summary to WhatsApp

Pros:

- No Gmail password needed
- No OAuth complexity
- Simple for user

Cons:

- Requires you to run email server
- Spam management issues
- Can't access old emails

Option 2: Zapier-Style Webhooks

User connects via third-party service:

User: Connects Gmail to Zapier
Zapier: Monitors new emails
Zapier: Sends webhook to your bot
Bot: Processes and summarizes

Pros:

- No credential storage
- User controls permissions
- More secure

Cons:

- Requires Zapier account ($20/month)
- More complex setup
- Dependency on third party

Option 3: Browser Extension

More advanced approach:

User installs Chrome extension
Extension: Reads Gmail in browser
Extension: Sends to bot API
Bot: Processes and returns summary

Pros:

- No server-side credential storage
- Works with any email provider
- User controls access

Cons:

- Need to build Chrome extension
- More complex architecture
- User must keep browser open

MY HONEST RECOMMENDATION

For Your MVP (First Version)

DON'T promise email integration.

Instead, focus on what actually works:

1. **WhatsApp/Telegram chat bot**
    - Ask questions, get AI answers
    - Generate text/code
    - This works 100% reliably
2. **Simple skills that don't need credentials**
    - Weather (free API)
    - News headlines (free API)
    - Currency conversion (free API)
    - Math calculations (no API needed)
3. **Code execution**
    - User sends code

    - Bot runs in sandbox
    - Returns results
    - This works reliably

For Version 2 (Later)

Add integrations properly:

1. Build OAuth flow correctly
2. Store tokens encrypted in database
3. Handle token refresh automatically
4. Clear documentation on setup
5. Support team to help users

BOTTOM LINE

The PDF example is misleading.

When it shows:

User: "Summarize my emails"
Bot: "You received 12 emails..."

Reality is:

User: "Summarize my emails"
Bot: "I don't have access to your Gmail.
Would you like to install the Gmail Skill?
You'll need to provide credentials."

For email to work, you need:

1. ✅ Email skill code written (not in PDF)
2. ✅ User provides Gmail credentials (security risk)
3. ✅ Handle OAuth or App Passwords (complex)
4. ✅ Deal with API limits and expiration (ongoing work)
5. ✅ Encrypt credential storage (not in PDF)
6. ✅ Handle errors when Gmail blocks access (common)

My advice:

Start without email integration. Get the basic WhatsApp AI bot working first. Add email later when you have users and can invest in doing it properly.

Does this honest explanation help? Want me to show you what skills ACTUALLY work out of the box?

BEST SETUP FOR EMAIL, CALENDAR & WEB BROWSING

I'll give you the **production-grade architecture** with industry best practices.

ARCHITECTURE OVERVIEW

```
┌──────────────
```

1. EMAIL INTEGRATION (BEST PRACTICE)

Architecture Choice: OAuth 2.0 (Not Passwords)

Why OAuth Over Passwords?

Method	Security	User Trust	Google Support	Auto-Refresh
Password	❌ Terrible	❌ Low	❌ Being deprecated	❌ No
App Password	⚠️ Medium	⚠️ Medium	⚠️ Limited	❌ No
OAuth 2.0	✅ Excellent	✅ High	✅ Recommended	✅ Yes

Implementation: Gmail OAuth Integration

Step 1: Google Cloud Setup (One-Time)

```
# You (platform owner) set up Google Cloud Project

1. Go to console.cloud.google.com
2. Create project: "ClawCloud"
3. Enable Gmail API
4. Create OAuth 2.0 Credentials:
   - Application type: Web application
   - Authorized redirect URIs: https://clawcloud.com/auth/gmail/callback
5. Get:
   - Client ID: 123456.apps.googleusercontent.com
   - Client Secret: GOCSPX-xxxxx
```

Step 2: User Authorization Flow

```
// File: /opt/claw-backend/integrations/gmail-auth.js

const { google } = require('googleapis');
const express = require('express');

const oauth2Client = new google.auth.OAuth2(
    process.env.GOOGLE_CLIENT_ID,
    process.env.GOOGLE_CLIENT_SECRET,
```

```
    'https://clawcloud.com/auth/gmail/callback'
);

// STEP 1: User clicks "Connect Gmail" in dashboard
app.get('/api/gmail/auth-url/:userId', (req, res) => {
    const authUrl = oauth2Client.generateAuthUrl({
        access_type: 'offline',  // Gets refresh token
        scope: [
            'https://www.googleapis.com/auth/gmail.readonly',
            'https://www.googleapis.com/auth/gmail.send'
        ],
        state: req.params.userId  // Track which user this is
    });

    res.json({ authUrl });
});

// STEP 2: Google redirects back with authorization code
app.get('/auth/gmail/callback', async (req, res) => {
    const { code, state: userId } = req.query;

    try {
        // Exchange code for tokens
        const { tokens } = await oauth2Client.getToken(code);

        /*
        tokens = {
            access_token: "ya29.a0AfH6...",     // Valid for 1 hour
            refresh_token: "1//0gXXX...",       // Valid forever
            scope: "https://www.googleapis.com/auth/gmail.readonly",
            token_type: "Bearer",
            expiry_date: 1704067200000
        }
        */

        // Save to database (ENCRYPTED)
        await saveTokens(userId, tokens);

        // Update container config
        await updateContainerSecrets(userId, {
            gmail_connected: true
        });

        res.redirect(`https://customer${userId}.clawcloud.com?status=gmail_connected`);

    } catch (error) {
        console.error('Gmail auth failed:', error);
        res.status(500).send('Authorization failed');
```

```
    }
});
```

Step 3: Token Storage (Encrypted)

```
// File: /opt/claw-backend/lib/token-manager.js

const crypto = require('crypto');
const { Pool } = require('pg');

const pool = new Pool({
    host: 'localhost',
    database: 'clawcloud',
    user: 'clawadmin',
    password: process.env.DB_PASSWORD
});

// Encryption key (store in environment, rotate regularly)
const ENCRYPTION_KEY = Buffer.from(process.env.TOKEN_ENCRYPTION_KEY, 'hex');
const IV_LENGTH = 16;

function encrypt(text) {
    const iv = crypto.randomBytes(IV_LENGTH);
    const cipher = crypto.createCipheriv('aes-256-cbc', ENCRYPTION_KEY, iv);

    let encrypted = cipher.update(text, 'utf8', 'hex');
    encrypted += cipher.final('hex');

    return iv.toString('hex') + ':' + encrypted;
}

function decrypt(text) {
    const parts = text.split(':');
    const iv = Buffer.from(parts[0], 'hex');
    const encryptedText = parts[1];

    const decipher = crypto.createDecipheriv('aes-256-cbc', ENCRYPTION_KEY, iv);

    let decrypted = decipher.update(encryptedText, 'hex', 'utf8');
    decrypted += decipher.final('utf8');

    return decrypted;
}

async function saveTokens(userId, tokens) {
    await pool.query(`
        INSERT INTO oauth_tokens (user_id, provider, access_token, refresh_token, expiry)
```

```
        VALUES ($1, 'gmail', $2, $3, $4)
        ON CONFLICT (user_id, provider)
        DO UPDATE SET
            access_token = $2,
            refresh_token = $3,
            expiry = $4,
            updated_at = NOW()
    `, [
        userId,
        encrypt(tokens.access_token),
        encrypt(tokens.refresh_token),
        new Date(tokens.expiry_date)
    ]);
}

async function getTokens(userId) {
    const result = await pool.query(`
        SELECT access_token, refresh_token, expiry
        FROM oauth_tokens
        WHERE user_id = $1 AND provider = 'gmail'
    `, [userId]);

    if (result.rows.length === 0) return null;

    return {
        access_token: decrypt(result.rows[0].access_token),
        refresh_token: decrypt(result.rows[0].refresh_token),
        expiry: result.rows[0].expiry
    };
}
```

Step 4: Auto-Refresh Token Logic

```
// File: /opt/claw-backend/integrations/gmail-service.js

const { google } = require('googleapis');

class GmailService {
    constructor(userId) {
        this.userId = userId;
        this.oauth2Client = new google.auth.OAuth2(
            process.env.GOOGLE_CLIENT_ID,
            process.env.GOOGLE_CLIENT_SECRET
        );
    }

    async ensureValidToken() {
```

```
    const tokens = await getTokens(this.userId);

    if (!tokens) {
        throw new Error('Gmail not connected');
    }

    // Check if token expired
    const now = Date.now();
    const expiry = new Date(tokens.expiry).getTime();

    if (now >= expiry - 300000) {  // Refresh 5 minutes before expiry
        console.log('Token expired, refreshing...');

        this.oauth2Client.setCredentials({
            refresh_token: tokens.refresh_token
        });

        const { credentials } = await this.oauth2Client.refreshAccessToken();

        // Save new access token
        await saveTokens(this.userId, credentials);

        return credentials.access_token;
    }

    return tokens.access_token;
}

async fetchEmails(maxResults = 10) {
    const accessToken = await this.ensureValidToken();

    this.oauth2Client.setCredentials({
        access_token: accessToken
    });

    const gmail = google.gmail({ version: 'v1', auth: this.oauth2Client });

    // Fetch email list
    const response = await gmail.users.messages.list({
        userId: 'me',
        maxResults,
        q: 'is:unread'  // Only unread emails
    });

    const messages = response.data.messages || [];

    // Fetch full content for each email
    const emails = await Promise.all(
```

```
        messages.map(async (msg) => {
            const email = await gmail.users.messages.get({
                userId: 'me',
                id: msg.id,
                format: 'full'
            });

            // Parse email
            const headers = email.data.payload.headers;
            const subject = headers.find(h => h.name === 'Subject')?.value || 'No Subject';
            const from = headers.find(h => h.name === 'From')?.value || 'Unknown';
            const date = headers.find(h => h.name === 'Date')?.value || '';

            // Get body (simplified)
            let body = '';
            if (email.data.payload.body.data) {
                body = Buffer.from(email.data.payload.body.data, 'base64').toString();
            }

            return { subject, from, date, body };
        })
    );

    return emails;
  }

  async summarizeEmails() {
    const emails = await this.fetchEmails(20);

    // Send to AI for summarization
    const prompt = `Summarize these emails concisely:\n\n${
        emails.map((e, i) =>
            `${i+1}. From: ${e.from}\n   Subject: ${e.subject}\n   Preview: ${e.body.slice(0,
200)}...`
        ).join('\n\n')
    }`;

    // Call OpenAI (using user's key from container)
    const summary = await callOpenAI(this.userId, prompt);

    return summary;
  }
}

module.exports = GmailService;
```

Step 5: Container Integration

```
// File: Inside user's container - /root/.openclaw/plugins/gmail.js

const GmailService = require('./gmail-service');

module.exports = {
    name: 'gmail',

    async handleMessage(userId, messageText) {
        if (messageText.toLowerCase().includes('summarize') &&
            messageText.toLowerCase().includes('email')) {

            try {
                const gmailService = new GmailService(userId);
                const summary = await gmailService.summarizeEmails();

                return {
                    response: `📧 Email Summary:\n\n${summary}`,
                    success: true
                };

            } catch (error) {
                if (error.message === 'Gmail not connected') {
                    return {
                        response: 'Gmail is not connected. Please connect in your dashboard:
https://customer' + userId + '.clawcloud.com/settings',
                        success: false
                    };
                }

                return {
                    response: 'Failed to fetch emails. Please try again.',
                    success: false
                };
            }
        }

        return null;  // Not a gmail command
    }
};
```

---

2. CALENDAR INTEGRATION (BEST PRACTICE)

Same OAuth Flow, Different Scopes

```
// File: /opt/claw-backend/integrations/calendar-service.js

const { google } = require('googleapis');

class CalendarService {
    constructor(userId) {
        this.userId = userId;
        this.oauth2Client = new google.auth.OAuth2(
            process.env.GOOGLE_CLIENT_ID,
            process.env.GOOGLE_CLIENT_SECRET
        );
    }

    async ensureValidToken() {
        // Same as Gmail (reuse token manager)
        const tokens = await getTokens(this.userId, 'calendar');

        if (!tokens) throw new Error('Calendar not connected');

        // Check expiry and refresh if needed
        // ... (same logic as Gmail)

        return tokens.access_token;
    }

    async createEvent(summary, startTime, endTime, description = '') {
        const accessToken = await this.ensureValidToken();

        this.oauth2Client.setCredentials({ access_token: accessToken });

        const calendar = google.calendar({ version: 'v3', auth: this.oauth2Client });

        const event = {
            summary,
            description,
            start: {
                dateTime: startTime,  // "2024-02-07T10:00:00-07:00"
                timeZone: 'America/Los_Angeles'
            },
            end: {
```

```
            dateTime: endTime,
            timeZone: 'America/Los_Angeles'
        },
        reminders: {
            useDefault: false,
            overrides: [
                { method: 'popup', minutes: 10 }
            ]
        }
    };

    const response = await calendar.events.insert({
        calendarId: 'primary',
        resource: event
    });

    return response.data;
}

async listUpcomingEvents(maxResults = 10) {
    const accessToken = await this.ensureValidToken();

    this.oauth2Client.setCredentials({ access_token: accessToken });

    const calendar = google.calendar({ version: 'v3', auth: this.oauth2Client });

    const response = await calendar.events.list({
        calendarId: 'primary',
        timeMin: new Date().toISOString(),
        maxResults,
        singleEvents: true,
        orderBy: 'startTime'
    });

    return response.data.items || [];
}

async parseAndCreateEvent(naturalLanguage) {
    // Example: "Schedule meeting with John tomorrow at 2pm for 1 hour"

    // Send to AI to parse
    const prompt = `Extract calendar event details from: "${naturalLanguage}"

    Return JSON with:
    - summary (string)
    - startTime (ISO 8601)
    - endTime (ISO 8601)
    - description (string)
```

```
        Current time: ${new Date().toISOString()}`;

        const aiResponse = await callOpenAI(this.userId, prompt);
        const eventDetails = JSON.parse(aiResponse);

        // Create the event
        const event = await this.createEvent(
            eventDetails.summary,
            eventDetails.startTime,
            eventDetails.endTime,
            eventDetails.description
        );

        return event;
    }
}

module.exports = CalendarService;
```

---

3. WEB BROWSING (BEST PRACTICE)

Architecture: Headless Browser in Sidecar Container

Why Headless Browser?

Method	Can Handle JS	Can Login	Can Screenshot	Cost
curl/wget	❌ No	❌ No	❌ No	Free
Puppeteer	✅ Yes	✅ Yes	✅ Yes	Medium
Playwright	✅ Yes	✅ Yes	✅ Yes	Medium
Selenium	✅ Yes	✅ Yes	✅ Yes	Heavy

Best Choice: Playwright (faster, more reliable than Puppeteer)

Implementation: Web Browsing Service

Step 1: Add Browser Sidecar to Docker Compose

```
# File: /opt/users/{userId}/docker-compose.yml

version: '3.8'

services:
  openclaw:
    image: openclaw/openclaw:latest
    container_name: claw-${USER_ID}
    restart: always
    ports:
      - "${USER_PORT}:18789"
    volumes:
      - ./config:/root/.openclaw
    environment:
      - OPENCLAW_API_PASSWORD=${PASSWORD}
      - OPENAI_API_KEY=${OPENAI_KEY}
      - BROWSER_SERVICE_URL=http://browser:3001
    depends_on:
      - browser
    networks:
      - claw-network

  browser:
    image: mcr.microsoft.com/playwright:v1.40.0-focal
    container_name: claw-${USER_ID}-browser
    restart: always
    command: node /app/browser-service.js
    volumes:
      - ./browser-service:/app
    environment:
      - NODE_ENV=production
    networks:
      - claw-network
    mem_limit: 1g
    cpus: 0.5

networks:
  claw-network:
    driver: bridge
```

Step 2: Browser Service Code

```
// File: /opt/users/{userId}/browser-service/browser-service.js

const express = require('express');
const { chromium } = require('playwright');
```

```
const app = express();
app.use(express.json());

let browser;
let context;

// Initialize browser on startup
async function initBrowser() {
    browser = await chromium.launch({
        headless: true,
        args: [
            '--no-sandbox',
            '--disable-setuid-sandbox',
            '--disable-dev-shm-usage',
            '--disable-gpu'
        ]
    });

    context = await browser.newContext({
        userAgent: 'Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36',
        viewport: { width: 1920, height: 1080 }
    });

    console.log('Browser initialized');
}

initBrowser().catch(console.error);

// Endpoint: Fetch page content
app.post('/fetch', async (req, res) => {
    const { url, waitForSelector, screenshot } = req.body;

    try {
        const page = await context.newPage();

        // Set timeout
        page.setDefaultTimeout(30000);

        // Navigate to URL
        await page.goto(url, { waitUntil: 'networkidle' });

        // Wait for specific element if requested
        if (waitForSelector) {
            await page.waitForSelector(waitForSelector);
        }

        // Extract content
```

```
        const content = await page.evaluate(() => {
            // Remove scripts, styles
            const scripts = document.querySelectorAll('script, style, noscript');
            scripts.forEach(s => s.remove());

            // Get text content
            return {
                title: document.title,
                text: document.body.innerText,
                html: document.body.innerHTML,
                links: Array.from(document.querySelectorAll('a')).map(a => ({
                    text: a.innerText,
                    href: a.href
                }))
            };
        });

        let screenshotData = null;
        if (screenshot) {
            screenshotData = await page.screenshot({
                type: 'png',
                fullPage: false
            });
        }

        await page.close();

        res.json({
            success: true,
            url,
            content,
            screenshot: screenshotData ? screenshotData.toString('base64') : null
        });

    } catch (error) {
        console.error('Browse error:', error);
        res.status(500).json({
            success: false,
            error: error.message
        });
    }
});

// Endpoint: Search Google
app.post('/search', async (req, res) => {
    const { query, maxResults = 5 } = req.body;

    try {
```

```
        const page = await context.newPage();

        // Go to Google
        await page.goto('https://www.google.com/search?q=' + encodeURIComponent(query));

        // Wait for results
        await page.waitForSelector('#search');

        // Extract search results
        const results = await page.evaluate((max) => {
            const items = [];
            const resultDivs = document.querySelectorAll('#search .g');

            for (let i = 0; i < Math.min(resultDivs.length, max); i++) {
                const div = resultDivs[i];

                const titleEl = div.querySelector('h3');
                const linkEl = div.querySelector('a');
                const snippetEl = div.querySelector('.VwiC3b, .yXK7lf');

                if (titleEl && linkEl) {
                    items.push({
                        title: titleEl.innerText,
                        url: linkEl.href,
                        snippet: snippetEl ? snippetEl.innerText : ''
                    });
                }
            }

            return items;
        }, maxResults);

        await page.close();

        res.json({
            success: true,
            query,
            results
        });

    } catch (error) {
        console.error('Search error:', error);
        res.status(500).json({
            success: false,
            error: error.message
        });
    }
});
```

```
// Endpoint: Fill form and submit
app.post('/interact', async (req, res) => {
    const { url, actions } = req.body;

    /*
    actions = [
        { type: 'fill', selector: '#email', value: 'user@example.com' },
        { type: 'fill', selector: '#password', value: 'secret' },
        { type: 'click', selector: 'button[type="submit"]' },
        { type: 'wait', milliseconds: 2000 }
    ]
    */

    try {
        const page = await context.newPage();
        await page.goto(url);

        for (const action of actions) {
            switch (action.type) {
                case 'fill':
                    await page.fill(action.selector, action.value);
                    break;
                case 'click':
                    await page.click(action.selector);
                    break;
                case 'wait':
                    await page.waitForTimeout(action.milliseconds);
                    break;
                case 'waitForSelector':
                    await page.waitForSelector(action.selector);
                    break;
            }
        }

        // Get final page content
        const finalUrl = page.url();
        const content = await page.content();

        await page.close();

        res.json({
            success: true,
            finalUrl,
            content
        });

    } catch (error) {
```

```
        console.error('Interact error:', error);
        res.status(500).json({
            success: false,
            error: error.message
        });
    }
});

app.listen(3001, () => {
    console.log('Browser service running on port 3001');
});
```

Step 3: Integration with OpenClaw

```
// File: Inside user's container - /root/.openclaw/plugins/web-browser.js

const axios = require('axios');

const BROWSER_SERVICE = process.env.BROWSER_SERVICE_URL ||
'http://browser:3001';

module.exports = {
    name: 'web-browser',

    async handleMessage(userId, messageText) {
        const lower = messageText.toLowerCase();

        // Command: "search for X"
        if (lower.startsWith('search for ') || lower.startsWith('google ')) {
            const query = messageText.replace(/^(search for|google)\s+/i, '');

            try {
                const response = await axios.post(`${BROWSER_SERVICE}/search`, {
                    query,
                    maxResults: 5
                });

                const results = response.data.results;

                let message = `🔍 Search results for "${query}":\n\n`;
                results.forEach((r, i) => {
                    message += `${i+1}. ${r.title}\n   ${r.url}\n   ${r.snippet}\n\n`;
                });

                return { response: message, success: true };

            } catch (error) {
```

```
            return {
                response: 'Search failed: ' + error.message,
                success: false
            };
        }
    }

    // Command: "visit https://example.com"
    if (lower.startsWith('visit ') || lower.startsWith('browse ')) {
        const url = messageText.match(/https?:\/\/[^\s]+/)?.[0];

        if (!url) {
            return {
                response: 'Please provide a valid URL',
                success: false
            };
        }

        try {
            const response = await axios.post(`${BROWSER_SERVICE}/fetch`, {
                url,
                screenshot: false
            });

            const content = response.data.content;

            // Summarize with AI
            const summary = await summarizeWebpage(content.text);

            return {
                response: `📄 ${content.title}\n\n${summary}`,
                success: true
            };

        } catch (error) {
            return {
                response: 'Failed to browse: ' + error.message,
                success: false
            };
        }
    }

    return null;  // Not a browser command
  }
};

async function summarizeWebpage(text) {
  // Truncate to first 3000 chars
```

```
    const truncated = text.slice(0, 3000);

    const prompt = `Summarize this webpage in 3-4 sentences:\n\n${truncated}`;

    // Call OpenAI
    return await callOpenAI(userId, prompt);
}
```

DATABASE SCHEMA

```
-- Complete schema for all integrations

CREATE TABLE customers (
    id SERIAL PRIMARY KEY,
    customer_id VARCHAR(50) UNIQUE NOT NULL,
    subdomain VARCHAR(100) UNIQUE NOT NULL,
    port INTEGER UNIQUE NOT NULL,
    password VARCHAR(100) NOT NULL,
    created_at TIMESTAMP DEFAULT NOW(),
    last_active TIMESTAMP,
    status VARCHAR(20) DEFAULT 'active'
);

CREATE TABLE oauth_tokens (
    id SERIAL PRIMARY KEY,
    user_id VARCHAR(50) REFERENCES customers(customer_id) ON DELETE CASCADE,
    provider VARCHAR(50) NOT NULL,  -- 'gmail', 'calendar', 'dropbox', etc.
    access_token TEXT NOT NULL,     -- Encrypted
    refresh_token TEXT NOT NULL,    -- Encrypted
    expiry TIMESTAMP NOT NULL,
    scopes TEXT[],                  -- ['gmail.readonly', 'gmail.send']
    created_at TIMESTAMP DEFAULT NOW(),
    updated_at TIMESTAMP DEFAULT NOW(),
    UNIQUE(user_id, provider)
);

CREATE TABLE integration_logs (
    id SERIAL PRIMARY KEY,
    user_id VARCHAR(50) REFERENCES customers(customer_id) ON DELETE CASCADE,
    integration VARCHAR(50) NOT NULL,  -- 'gmail', 'calendar', 'browser'
    action VARCHAR(100) NOT NULL,       -- 'fetch_emails', 'create_event', 'search'
    success BOOLEAN NOT NULL,
    error_message TEXT,
    timestamp TIMESTAMP DEFAULT NOW()
```

```
);

CREATE INDEX idx_oauth_tokens_user ON oauth_tokens(user_id, provider);
CREATE INDEX idx_integration_logs_user ON integration_logs(user_id, timestamp);
```

SECURITY BEST PRACTICES

1. Token Encryption

```
// Never store tokens in plain text
// Always encrypt with AES-256-CBC

const crypto = require('crypto');

const ALGORITHM = 'aes-256-cbc';
const ENCRYPTION_KEY = Buffer.from(process.env.TOKEN_ENCRYPTION_KEY, 'hex');
// Generate once: crypto.randomBytes(32).toString('hex')

function encrypt(text) {
  const iv = crypto.randomBytes(16);
  const cipher = crypto.createCipheriv(ALGORITHM, ENCRYPTION_KEY, iv);

  let encrypted = cipher.update(text, 'utf8', 'hex');
  encrypted += cipher.final('hex');

  return iv.toString('hex') + ':' + encrypted;
}

function decrypt(text) {
  const [ivHex, encryptedText] = text.split(':');
  const iv = Buffer.from(ivHex, 'hex');
  const decipher = crypto.createDecipheriv(ALGORITHM, ENCRYPTION_KEY, iv);

  let decrypted = decipher.update(encryptedText, 'hex', 'utf8');
  decrypted += decipher.final('utf8');

  return decrypted;
}
```

2. Rate Limiting

```
// Prevent abuse of integrations
```

```
const rateLimit = require('express-rate-limit');

const gmailLimiter = rateLimit({
    windowMs: 15 * 60 * 1000,  // 15 minutes
    max: 50,  // Max 50 requests per 15 minutes per user
    keyGenerator: (req) => req.body.userId,
    message: 'Too many Gmail requests, please try again later'
});

app.post('/api/gmail/fetch', gmailLimiter, async (req, res) => {
    // ... gmail logic
});
```

3. Scope Limitation

```
// Only request minimum necessary permissions

const GMAIL_SCOPES = [
    'https://www.googleapis.com/auth/gmail.readonly',  // Read only
    // NOT 'https://www.googleapis.com/auth/gmail.modify'  // Too broad
];

const CALENDAR_SCOPES = [
    'https://www.googleapis.com/auth/calendar.events',  // Specific to events
    // NOT 'https://www.googleapis.com/auth/calendar'  // Too broad
];
```

4. Browser Sandboxing

```
# Isolate browser container
browser:
  # Resource limits
  mem_limit: 1g
  cpus: 0.5

  # No network except to main container
  networks:
    - claw-network

  # Read-only filesystem
  read_only: true
  tmpfs:
    - /tmp

  # Drop all capabilities
```

```
cap_drop:
  - ALL
```

WHY THESE ARE BEST PRACTICES (SIMPLE EXPLANATION)

1. Why OAuth Instead of Passwords?

With Passwords:

User gives you: password123
You store: password123
Google sees: Login from unknown server
Google: "Suspicious activity! Block this!"
User: "Why can't I access my email?"

With OAuth:

User clicks: "Allow ClawCloud to read emails"
Google gives you: Token (temporary key, not password)
Token expires: Automatically refreshes
User revokes: Token stops working instantly
You never see: User's actual password

Benefits:

- ✅ User can revoke access anytime
- ✅ Token auto-refreshes (user never re-authenticates)
- ✅ Google trusts OAuth (won't block)
- ✅ If you get hacked, attacker can't login to Gmail (they only have token)

---

2. Why Encrypt Tokens in Database?

Without Encryption:

Hacker gets your database
Hacker sees: access_token = "ya29.a0AfH6..."
Hacker uses: Token to access ALL user emails
Result: Data breach, lawsuits, business destroyed

With Encryption:

Hacker gets your database
Hacker sees: access_token = "8f7a:9c2b4e..."
Hacker tries: Can't decrypt without encryption key
Result: Tokens are useless to hacker

Benefits:

- ✅ Database leak doesn't expose tokens
- ✅ Encryption key stored separately (environment variable)
- ✅ Compliance with GDPR, CCPA regulations
- ✅ User trust

---

3. Why Headless Browser Instead of Simple HTTP?

With Simple HTTP (curl):

Your bot: "GET https://nytimes.com"
NYTimes: Returns HTML
Problem 1: HTML has no content (loaded by JavaScript)
Problem 2: Can't handle login forms
Problem 3: Can't take screenshots
Problem 4: Can't click buttons

With Headless Browser (Playwright):

Your bot: "Open https://nytimes.com"
Browser: Loads page, runs JavaScript, renders content
Bot: Can see full content, take screenshot, click buttons

Real Example:

User: "Check my Amazon orders"

With curl:
- Can't login (needs cookies, CSRF tokens)
- Can't see order list (loaded by JavaScript)
- FAILS

With Playwright:
- Opens Amazon

- Fills login form
- Waits for page load
- Extracts order data
- WORKS

---

4. Why Sidecar Container for Browser?

All in One Container:

Main container: 200MB RAM
Add browser: +800MB RAM
Total: 1GB per customer
100 customers: 100GB RAM needed
Cost: $200/month server

Separate Sidecar:

Main container: 200MB RAM
Browser sidecar: Only when needed
Most customers: Don't use browser constantly
Average usage: 300MB per customer
100 customers: 30GB RAM needed
Cost: $40/month server

Benefits:

- ✅ Saves RAM (browser only runs when needed)
- ✅ Crashes isolated (browser crash doesn't kill main bot)
- ✅ Easy to update (upgrade browser without touching main app)
- ✅ Can disable per customer (not everyone needs browsing)

---

5. Why Auto-Refresh Tokens?

Without Auto-Refresh:

Day 1: User connects Gmail
Day 2-30: Works fine
Day 31: Token expires
Bot: "Gmail not connected"
User: "Why do I have to reconnect every month??"
User: Cancels subscription

With Auto-Refresh:

Day 1: User connects Gmail (gets refresh_token)
Day 30: access_token about to expire
Bot: Automatically uses refresh_token to get new access_token
User: Never knows anything happened
Works: Forever (unless user revokes access)

Benefits:

- ✅ Zero user intervention
- ✅ Seamless experience
- ✅ Higher retention rates
- ✅ Less support tickets

---

6. Why Rate Limiting?

Without Rate Limiting:

Malicious user: Sends 10,000 "search Google" commands
Your server: Makes 10,000 browser requests
Google: "This IP is abusing our service" → BANS your IP
Result: ALL customers can't search anymore

With Rate Limiting:

Malicious user: Sends 10,000 commands
Your server: Processes first 50, blocks rest
Response: "Too many requests, try again in 15 minutes"
Google: Sees normal traffic
Result: Service stays online for everyone

Benefits:

- ✅ Prevents abuse
- ✅ Protects infrastructure
- ✅ Fair usage for all customers
- ✅ Avoids API bans

---

7. Why Separate Networks for Containers?

No Network Isolation:

Customer A's container: Can ping Customer B's container
Malicious Customer A: Scans network, finds Customer B
Customer A: Sends requests to Customer B's services
Result: Cross-customer data access

With Docker Networks:

Customer A's network: claw-network-A
Customer B's network: claw-network-B
Customer A tries: Can't even see Customer B exists
Result: Complete isolation

Benefits:

- ✅ Zero cross-customer access
- ✅ Compliance with security standards
- ✅ Prevents lateral movement in attacks
- ✅ Each customer is truly isolated

FINAL SIMPLIFIED SUMMARY

What You're Building

For Email:

1. User clicks "Connect Gmail" → Google OAuth flow
2. You get token (not password) → Store encrypted in database
3. Token refreshes automatically → User never re-authenticates
4. Bot can read/send emails → Using Gmail API

For Calendar:

1. Same OAuth flow as Gmail → Different scopes
2. Bot can read/create events → Using Calendar API
3. AI parses natural language → "Schedule meeting tomorrow at 2pm"
4. Creates actual calendar event → Appears in user's Google Calendar

For Web Browsing:

1. Separate browser container → Runs Playwright
2. User asks: "Search for best coffee shops"

3. Browser opens Google → Extracts results
4. AI summarizes → Sends to user

Why This Way Is Best

Method	Our Approach	Why
Email	OAuth tokens	Secure, auto-refreshes, user controls access
Storage	Encrypted DB	Database leak doesn't expose real tokens
Browser	Headless Playwright	Handles JavaScript, login forms, screenshots
Architecture	Sidecar containers	Saves RAM, isolates crashes, scales better
Tokens	Auto-refresh	Works forever without user intervention
Security	Rate limits + isolation	Prevents abuse and cross-customer access

Production Checklist

- [ ] Set up Google Cloud OAuth credentials
- [ ] Implement token encryption (AES-256)
- [ ] Add auto-refresh logic
- [ ] Deploy browser sidecar container
- [ ] Add rate limiting middleware
- [ ] Set up PostgreSQL with proper schema
- [ ] Test OAuth flow end-to-end
- [ ] Test token refresh after 1 hour
- [ ] Test browser search/fetch
- [ ] Monitor resource usage

Time to implement: 1-2 weeks with testing

Result: Professional, secure, scalable integration system that actually works in production.

Does this make sense now? Which part needs more clarification?

COMPLETE TOOLS & REQUIREMENTS LIST

I'll list EVERYTHING you need to build this system, organized by category.

---

1. SERVER & HOSTING

Primary Server

Provider: Hetzner
Plan: CX41
Specs:
- 4 vCPU cores
- 16 GB RAM
- 160 GB SSD
- 20 TB traffic

Cost: €17/month (~$18/month)
OS: Ubuntu 24.04 LTS

Alternative providers:
- DigitalOcean ($84/month for similar specs)
- Vultr ($60/month)
- AWS Lightsail ($40/month but limited)

Recommendation: Start with Hetzner (cheapest, reliable)

Domain Name

Provider: Namecheap, GoDaddy, or Cloudflare
Example: clawcloud.com
Cost: $10-15/year

Requirements:
- Must support DNS management
- Will point to Cloudflare nameservers

DNS Management

Service: Cloudflare (Free plan)
Why needed: Required for wildcard SSL automation
Features used:
- DNS hosting
- API for Let's Encrypt DNS challenge
- DDoS protection (bonus)

Cost: Free

---

2. SOFTWARE ON SERVER

Core System Software

These get installed on your server

1. Docker
   - What: Containerization platform
   - Why: Runs isolated customer environments
   - Install: apt install docker.io

2. Docker Compose
   - What: Multi-container orchestration
   - Why: Manages customer containers easily
   - Install: apt install docker-compose

3. Nginx
   - What: Web server / reverse proxy
   - Why: Routes traffic to correct container
   - Install: apt install nginx

4. Certbot
   - What: SSL certificate manager
   - Why: Gets free SSL from Let's Encrypt
   - Install: apt install certbot

5. Certbot DNS Plugin
   - What: Cloudflare integration for Certbot
   - Why: Automates wildcard SSL verification
   - Install: apt install python3-certbot-dns-cloudflare

6. PostgreSQL
   - What: Database
   - Why: Stores customer data, tokens, port assignments
   - Install: apt install postgresql postgresql-contrib

7. UFW (Firewall)
   - What: Ubuntu firewall
   - Why: Security - block unwanted ports
   - Install: apt install ufw (usually pre-installed)

8. Git
   - What: Version control
   - Why: Deploy your code
   - Install: apt install git

9. Node.js
   - What: JavaScript runtime

- Why: Runs your backend API
- Install: curl -fsSL https://deb.nodesource.com/setup_20.x | bash -
  apt install nodejs

10. npm
    - What: Node package manager
    - Why: Install JavaScript libraries
    - Install: Comes with Node.js

---

3. BACKEND DEPENDENCIES (Node.js Packages)

For Main API Server

```
# File: /opt/claw-backend/package.json

npm install express          # Web framework
npm install pg               # PostgreSQL client
npm install dotenv           # Environment variables
npm install bcrypt           # Password hashing
npm install jsonwebtoken     # JWT tokens for auth
npm install express-rate-limit # Rate limiting
npm install helmet           # Security headers
npm install cors             # Cross-origin requests
npm install winston          # Logging
npm install node-cron        # Scheduled tasks
npm install stripe           # Payment processing
```

For OAuth Integrations

```
npm install googleapis       # Google APIs (Gmail, Calendar)
npm install axios            # HTTP requests
npm install crypto           # Encryption (built-in Node.js)
```

For Container Management

```
npm install dockerode        # Docker API client
npm install proper-lockfile  # File locking (prevent race conditions)
```

---

4. BROWSER SERVICE DEPENDENCIES

For Headless Browser Container

```
# File: /opt/claw-platform/templates/browser-service/package.json

npm install express          # API server
npm install playwright       # Headless browser
```

Browser Container Image

```
# Use official Playwright image
FROM mcr.microsoft.com/playwright:v1.40.0-focal

# This includes:
# - Node.js
# - Chromium browser
# - All necessary dependencies
```

---

5. OPENCLAW (THE MAIN BOT SOFTWARE)

OpenClaw Installation

```
# OpenClaw is the WhatsApp/Telegram bot software
# (Note: I'm assuming this exists - if not, you'd build it)

Docker Image: openclaw/openclaw:latest

What it includes:
  - WhatsApp Web client
  - Telegram bot client
  - Message routing
  - Plugin system
  - Web UI for QR codes

Alternative if OpenClaw doesn't exist:
  - Use whatsapp-web.js (npm package)
  - Use node-telegram-bot-api (npm package)
```

OpenClaw Dependencies (Inside Container)

```
npm install whatsapp-web.js   # WhatsApp integration
npm install qrcode-terminal   # QR code display
npm install node-telegram-bot-api # Telegram integration
npm install openai            # OpenAI API
npm install anthropic         # Claude API (optional)
```

---

6. DATABASE TOOLS

PostgreSQL Setup

```
# After installing PostgreSQL

sudo -u postgres psql        # Access PostgreSQL

# Create database
CREATE DATABASE clawcloud;

# Create user
CREATE USER clawadmin WITH PASSWORD 'your_secure_password';

# Grant permissions
GRANT ALL PRIVILEGES ON DATABASE clawcloud TO clawadmin;
```

Database Management Tools (Optional)

pgAdmin (GUI tool)
- What: Visual database manager
- Why: Easier than command line
- Install: Download from pgadmin.org

DBeaver (Alternative)
- What: Universal database tool
- Why: Works with many databases
- Install: Download from dbeaver.io

psql (Command line)
- What: PostgreSQL command line
- Why: Quick queries and scripts
- Install: Comes with PostgreSQL

---

7. EXTERNAL SERVICES & APIs

Payment Processing

Stripe
- What: Payment processor
- Why: Handle customer subscriptions
- Cost: 2.9% + $0.30 per transaction
- Signup: stripe.com
- Need: API keys (test + live)

Email Service (For Sending Emails to Users)

Option 1: SendGrid
- Cost: Free up to 100 emails/day
- Signup: sendgrid.com

Option 2: Mailgun
- Cost: Free up to 5,000 emails/month
- Signup: mailgun.com

Option 3: AWS SES
- Cost: $0.10 per 1,000 emails
- Signup: aws.amazon.com

Recommendation: Start with SendGrid free tier

SMS Service (Optional - for 2FA)

Twilio
- What: SMS API
- Why: Send verification codes
- Cost: $0.0075 per SMS
- Signup: twilio.com

Backup Storage

Option 1: Backblaze B2
- Cost: $0.005/GB/month (cheapest)
- Signup: backblaze.com

Option 2: AWS S3
- Cost: $0.023/GB/month
- Signup: aws.amazon.com

Option 3: Hetzner Storage Box
- Cost: €3.81/month for 1TB
- Included with Hetzner account

Recommendation: Backblaze (cheapest)

Monitoring Service

Option 1: UptimeRobot
- What: Server uptime monitoring
- Cost: Free for 50 monitors
- Signup: uptimerobot.com

Option 2: Prometheus + Grafana (Self-hosted)
- What: Metrics and dashboards
- Cost: Free (runs on your server)
- Setup: More complex but powerful

---

8. GOOGLE CLOUD SERVICES

For OAuth Integration

Google Cloud Console
- What: Google's developer platform
- Why: Get OAuth credentials for Gmail/Calendar
- Cost: Free (API usage is free for most use)
- Signup: console.cloud.google.com

What you'll create:
1. New Project: "ClawCloud"

2. Enable APIs:
   - Gmail API
   - Google Calendar API

3. Create OAuth 2.0 Credentials:
   - Application type: Web application
   - Authorized redirect URIs: https://clawcloud.com/auth/callback

4. Get Credentials:
   - Client ID: 123456-abc.apps.googleusercontent.com
   - Client Secret: GOCSPX-xxxxxxxxxxxxx

---

9. DEVELOPMENT TOOLS

On Your Local Computer

1. Code Editor
   - VS Code (recommended)
   - Download: code.visualstudio.com
   - Extensions needed:
     * JavaScript/Node.js
     * Docker
     * PostgreSQL
     * GitLens

2. Terminal/SSH Client
   - Windows: PuTTY or Windows Terminal
   - Mac/Linux: Built-in terminal

3. Git
   - Download: git-scm.com
   - For version control

4. Docker Desktop (Optional)
   - What: Run Docker locally for testing
   - Download: docker.com/products/docker-desktop

5. Postman
   - What: API testing tool
   - Download: postman.com
   - Why: Test your API endpoints

6. Node.js (Local)
   - Download: nodejs.org
   - For local development

---

10. SECURITY TOOLS

SSL Certificate Management

Let's Encrypt
  - What: Free SSL certificates
  - Why: HTTPS for all customer subdomains
  - Cost: Free
  - Tool: Certbot (already listed above)

Password/Secret Management

1. Environment Variables
   - File: .env
   - Store: API keys, database passwords
   - Tool: dotenv package (already listed)

2. Password Generator
   - Tool: pwgen (Linux command)
   - Install: apt install pwgen
   - Use: Generate random passwords for customers

Encryption Key Generation

```
# Generate encryption key for token storage
node -e "console.log(require('crypto').randomBytes(32).toString('hex'))"

# Store in environment variable
# Never commit to git!
```

---

11. FRONTEND TOOLS

For Customer Dashboard

```
1. React
   - Framework: Create React App or Vite
   - Install: npx create-react-app customer-dashboard

2. UI Library (Choose one):

   Option A: Tailwind CSS (Recommended)
   - Install: npm install tailwindcss
   - Why: Fast, customizable

   Option B: Material-UI
   - Install: npm install @mui/material
   - Why: Pre-built components

   Option C: Chakra UI
   - Install: npm install @chakra-ui/react
   - Why: Accessible, modern

3. Additional Frontend Packages:
   npm install react-router-dom  # Page routing
   npm install axios             # API calls
   npm install react-query       # Data fetching
   npm install recharts          # Charts/graphs (optional)
   npm install react-toastify    # Notifications
```

---

12. OPTIONAL BUT RECOMMENDED TOOLS

Logging & Error Tracking

```
Sentry
  - What: Error tracking
  - Why: Know when things break
  - Cost: Free up to 5,000 events/month
```

- Signup: sentry.io
- Install: npm install @sentry/node

Analytics

PostHog
- What: Open-source analytics
- Why: Track user behavior
- Cost: Free up to 1M events/month
- Signup: posthog.com
- Install: npm install posthog-node

Documentation

Swagger/OpenAPI
- What: API documentation
- Why: Document your API endpoints
- Install: npm install swagger-ui-express
- Install: npm install swagger-jsdoc

---

13. TESTING TOOLS

1. Jest
   - What: JavaScript testing framework
   - Install: npm install --save-dev jest

2. Supertest
   - What: HTTP testing
   - Install: npm install --save-dev supertest

3. Docker Compose (for test environments)
   - Already installed
   - Use: Spin up test databases

COMPLETE INSTALLATION SCRIPT

Here's a single script to install everything on your server:

```
#!/bin/bash
# File: setup-server.sh

echo "🚀 ClawCloud Server Setup Script"
```

```
# Update system
echo "📦 Updating system..."
apt update && apt upgrade -y

# Install core software
echo "🐳 Installing Docker..."
apt install -y docker.io docker-compose

# Install Nginx
echo "🌐 Installing Nginx..."
apt install -y nginx

# Install Certbot
echo "🔒 Installing SSL tools..."
apt install -y certbot python3-certbot-dns-cloudflare

# Install PostgreSQL
echo "💾 Installing PostgreSQL..."
apt install -y postgresql postgresql-contrib

# Install Node.js 20.x
echo "⚡ Installing Node.js..."
curl -fsSL https://deb.nodesource.com/setup_20.x | bash -
apt install -y nodejs

# Install utilities
echo "🛠️ Installing utilities..."
apt install -y git ufw htop vim curl wget

# Configure firewall
echo "🔥 Configuring firewall..."
ufw allow 22/tcp    # SSH
ufw allow 80/tcp    # HTTP
ufw allow 443/tcp   # HTTPS
ufw --force enable

# Create swap file (8GB)
echo "💿 Creating swap file..."
fallocate -l 8G /swapfile
chmod 600 /swapfile
mkswap /swapfile
swapon /swapfile
echo '/swapfile none swap sw 0 0' >> /etc/fstab

# Create directory structure
echo "📁 Creating directories..."
mkdir -p /opt/claw-backend
```

```
mkdir -p /opt/claw-platform/templates
mkdir -p /opt/claw-platform/users
mkdir -p /opt/backups
mkdir -p /etc/letsencrypt/secrets

# Set up PostgreSQL
echo "🗄️ Setting up PostgreSQL..."
sudo -u postgres psql -c "CREATE DATABASE clawcloud;"
sudo -u postgres psql -c "CREATE USER clawadmin WITH PASSWORD
'CHANGE_THIS_PASSWORD';"
sudo -u postgres psql -c "GRANT ALL PRIVILEGES ON DATABASE clawcloud TO
clawadmin;"

echo "✅ Server setup complete!"
echo ""
echo "Next steps:"
echo "1. Configure Cloudflare DNS"
echo "2. Get Cloudflare API token"
echo "3. Generate wildcard SSL certificate"
echo "4. Clone your application code"
echo "5. Set up environment variables"
```

COST BREAKDOWN

One-Time Costs

Domain name: $10-15 (yearly)
Total one-time: $10-15

Monthly Recurring Costs

REQUIRED:
Hetzner server: $18/month
Domain (monthly): $1/month
Backups (Backblaze): $2-5/month
SUBTOTAL: $21-24/month

OPTIONAL:
Monitoring: Free (UptimeRobot)
Email sending: Free (SendGrid 100/day)
Error tracking: Free (Sentry 5k events)
Analytics: Free (PostHog 1M events)

TOTAL MONTHLY: $21-24/month

Per-Transaction Costs

Stripe fees: 2.9% + $0.30 per payment
Example: $20 payment = $0.88 fee (you get $19.12)

QUICK START CHECKLIST

Week 1: Setup

- [ ] Buy domain name
- [ ] Sign up for Hetzner server
- [ ] Point domain to Cloudflare
- [ ] SSH into server
- [ ] Run setup script
- [ ] Generate SSL certificate

Week 2: Development

- [ ] Clone/create backend code
- [ ] Set up PostgreSQL database
- [ ] Install Node.js dependencies
- [ ] Configure environment variables
- [ ] Test provisioning API

Week 3: Integrations

- [ ] Set up Google Cloud project
- [ ] Get OAuth credentials
- [ ] Implement Gmail integration
- [ ] Implement Calendar integration
- [ ] Set up browser service

Week 4: Frontend

- [ ] Build customer dashboard
- [ ] Integrate Stripe payments
- [ ] Create user signup flow
- [ ] Test end-to-end

Week 5: Launch Prep

- [ ] Set up monitoring
- [ ] Configure backups
- [ ] Write Terms of Service
- [ ] Beta test with 5-10 users
- [ ] Fix bugs

Week 6: Launch

- [ ] Deploy to production
- [ ] Announce to public
- [ ] Monitor closely
- [ ] Iterate based on feedback

MINIMUM VIABLE PRODUCT (MVP) TOOLS

If you want to start ASAP with minimal tools:

ABSOLUTELY REQUIRED:
✅ Hetzner server ($18/month)
✅ Domain name ($10/year)
✅ Cloudflare (free)
✅ Docker + Nginx (free)
✅ PostgreSQL (free)
✅ Node.js (free)
✅ Stripe (2.9% + $0.30)

CAN SKIP FOR NOW:
❌ Backups (add after 10 customers)
❌ Monitoring (add after launch)
❌ Error tracking (add after launch)
❌ Analytics (add later)
❌ Gmail/Calendar integration (add v2)
❌ Browser service (add v2)

MVP = WhatsApp AI bot only
Cost = $18/month + Stripe fees
Time to build = 2-3 weeks

SUMMARY

Total tools needed: ~40

Categories:

- Server software: 10 tools
- Node.js packages: ~20 packages
- External services: 6 services
- Development tools: 5 tools
- Optional tools: 5 tools

Total monthly cost: $21-24

Time to set everything up: 4-6 weeks

Which tools do you want me to explain in more detail? Or should I create installation instructions for specific tools?

To set up **OpenClaw** (the open-source AI agent) on your own server using Docker, effectively replicating what the paid service "StartClaw" does but for free (minus server and API costs), follow this step-by-step guide.

This guide assumes you are starting from scratch.

Prerequisites

1. **A Cloud Server (VPS):** You need to rent a small Linux server.
    - **Recommended Specs:** Ubuntu 24.04 (or 22.04), at least **2GB RAM** (4GB is better), and 20GB storage.
    - **Providers:** DigitalOcean ($12-24/mo), Hetzner (~$5/mo), or Linode.
2. **API Keys:** You need an account with an AI provider (since you aren't paying StartClaw for credits).
    - **Anthropic (Claude):** Recommended for best performance. Get a key at `console.anthropic.com`.
    - **OpenAI (ChatGPT):** Get a key at `platform.openai.com`.

Phase 1: Connect to Your Server

Once you buy your server, the provider will email you an **IP Address** (e.g., `192.168.1.50`) and a **root password**.

1. **Open your Terminal** (on Mac/Linux) or **PowerShell** (on Windows).

Type the following command and press Enter:
Bash
ssh root@YOUR_SERVER_IP_ADDRESS

2. *(Replace `YOUR_SERVER_IP_ADDRESS` with the actual number).*
3. Type "yes" if asked to continue connecting.
4. Enter your password when prompted (the cursor won't move when you type, this is normal).

Phase 2: Install Docker (The Engine)

OpenClaw runs inside "containers" using Docker. You need to install this software first. Copy and run these commands one by one:

Update your server:
Bash
apt-get update && apt-get upgrade -y

1.

Install Docker:
Bash
curl -fsSL https://get.docker.com -o get-docker.sh
sh get-docker.sh

2.

Verify it works:
Bash
docker --version

3. *(If you see a version number like `Docker version 24.x.x`, you are ready).*

Phase 3: Download and Install OpenClaw

The official OpenClaw repository has a "magic script" that handles the complex Docker setup for you.

Install Git (to download the code):
Bash
apt-get install -y git

1.

Download OpenClaw:
Bash
git clone https://github.com/openclaw/openclaw.git

2.

Enter the folder:
Bash
cd openclaw

3.

Run the Setup Script:
Bash
./docker-setup.sh

4.

Phase 4: The Setup Wizard

The script will now ask you questions. Here is how to answer them for a standard setup:

1. **Gateway Mode:** Choose `Local` (since it's running on this server).
2. **Authentication:** It will ask to set up a **Gateway Token**.
   - The script might generate one for you automatically. **WRITE THIS DOWN.** You will need it to log in later.
3. **LLM Provider:** Select your provider (e.g., **Anthropic** or **OpenAI**).
   - Paste your **API Key** (starts with `sk-...`) when asked.
4. **Database:** Select `SQLite` (easiest for beginners) or `Postgres` (better for heavy use). Stick to SQLite if unsure.

Once finished, the script will automatically build the Docker containers. This might take 2-5 minutes.

Phase 5: Accessing Your Agent

Once the text stops scrolling and says the container is "Up" or "Running":

1. **Find your Dashboard URL:** The script usually outputs a URL at the end, often looking like: `http://YOUR_IP:3000?token=YOUR_LONG_TOKEN`
2. **Open in Browser:** Copy that full URL into your Chrome/Safari browser.
   - *Note: If the link is `localhost:3000`, replace "localhost" with your server's IP address.*
3. **Connect a Chat App (Telegram/WhatsApp):**
   - In the OpenClaw Dashboard, go to **Connections** or **Channels**.
   - **For Telegram:**
     1. Open Telegram app, search for `@BotFather`.
     2. Send `/newbot`, give it a name.
     3. BotFather will give you a **Token**.
     4. Paste that Token into the OpenClaw Dashboard.
   - **For WhatsApp:** Follow the QR code scanning instructions in the dashboard.

Troubleshooting & Security

- **"Site can't be reached":** Ensure your server provider (AWS/DigitalOcean) allows traffic on port **3000** (or whichever port OpenClaw used, sometimes 8080) in their "Firewall" settings.

Updating: To update OpenClaw in the future, go to the folder and run:
Bash
```
cd ~/openclaw
git pull
./docker-setup.sh
```

-
- **Security Warning:** Since you are running this on a public server, **never share your Dashboard URL with the token**. Anyone with that link can control your AI agent.

You now have a private, self-hosted version of the "StartClaw" service running on your own infrastructure.
